

# Solving for Utility

CS 480

Intro to Artificial Intelligence

# Definitions

**Utility** (17.2)

$S_0=s, S_1, S_2, S_3\dots$

$\downarrow$

$$U^\pi(s) = \mathbb{E}_{S_t \sim \pi} \left[ \sum_{t=0}^{\infty} \gamma^t R(S_t) \right]$$

**Optimal policy** (17.4)

$$\pi^*(s) = \arg \max_a \sum_{s'} p(s' \mid a, s) \cdot U^{\pi^*}(s')$$

# Bellman equation

If we **know**  $U^{\pi^*}(s)$ , we can compute the optimal policy. How do we find  $U^{\pi^*}(s)$ ?

**Answer:** the Bellman equation (17.5)

$$U^{\pi^*}(s) = R(s) + \gamma \max_a \sum_{s'} p(s' | a, s) U^{\pi^*}(s')$$

Where did this equation come from?

# Bellman proof (1)

Start with the definition 17.2 and see what we can do

Expectation facts

$$\mathbb{E}[A + B] = \mathbb{E}[A] + \mathbb{E}[B]$$

$$\mathbb{E}[c] = c$$

$$\begin{aligned} U^\pi(s) &= \mathbb{E}_{S_t \sim \pi} \left[ \sum_{t=0}^{\infty} \gamma^t R(S_t) \right] \\ &= \mathbb{E}_{S_t \sim \pi} \left[ \gamma^0 R(S_0) + \sum_{t=1}^{\infty} \gamma^t R(S_t) \right] \end{aligned}$$

**constant**

$$S_0 = s$$

$$= R(s) + \mathbb{E}_{S_t \sim \pi} \left[ \sum_{t=1}^{\infty} \gamma^t R(S_t) \right]$$

Not quite  $U^{\pi^*}(s')$

## Bellman proof (2)

$$S_0=s, S_1, S_2, S_3\dots$$

More expectation facts

$$\mathbb{E}[A] = \mathbb{E}[\mathbb{E}[A \mid B]]$$

$$\mathbb{E}[f(A)] = \sum_a f(A) \cdot p(A = a)$$

$$U^\pi(s) = R(s) + \mathbb{E}_{S_t \sim \pi} \left[ \sum_{t=1}^{\infty} \gamma^t R(S_t) \right]$$

$$S_0=s, S_1=s', S_2, S_3\dots$$

$$= R(s) + \mathbb{E}_{S_t \sim \pi} \left[ \mathbb{E}_{S_t \sim \pi} \left[ \sum_{t=1}^{\infty} \gamma^t R(S_t) \mid S_1 = s' \right] \right]$$

$$= R(s) + \sum_{s'} p(s' \mid \pi(s), s) \mathbb{E}_{S_t \sim \pi} \left[ \sum_{t=1}^{\infty} \gamma^t R(S_t) \mid S_1 = s' \right]$$

Getting closer, but now the index is off

## Bellman proof (3)

$$\begin{aligned}U^\pi(s) &= R(s) + \sum_{s'} p(s' \mid \pi(s), s) \mathbb{E}_{S_t \sim \pi} \left[ \sum_{t=1}^{\infty} \gamma^t R(S_t) \mid S_1 = s' \right] \\&= R(s) + \sum_{s'} p(s' \mid \pi(s), s) \mathbb{E}_{S_t \sim \pi} \left[ \gamma \sum_{t=0}^{\infty} \gamma^t R(S_t) \mid S_0 = s' \right] \\&= R(s) + \gamma \sum_{s'} p(s' \mid \pi(s), s) \mathbb{E}_{S_t \sim \pi} \left[ \sum_{t=0}^{\infty} \gamma^t R(S_t) \mid S_0 = s' \right] \\&= R(s) + \gamma \sum_{s'} p(s' \mid \pi(s), s) U^\pi(s')\end{aligned}$$

Can't compute this if we don't know  $\pi$ , what to do?

Optimal policy

$$\pi^*(s) = \arg \max_a \sum_{s'} p(s' | a, s) \cdot U^{\pi^*}(s')$$

Bellman proof (4)

$$U^\pi(s) = R(s) + \gamma \sum_{s'} p(s' | \pi(s), s) U^\pi(s')$$

$$U^{\pi^*}(s) = R(s) + \gamma \sum_{s'} p(s' | \pi^*(s), s) U^{\pi^*}(s')$$

$$= R(s) + \gamma \max_a \sum_{s'} p(s' | a, s) U^{\pi^*}(s')$$

Proof done!

# Using Bellman

$$U^{\pi^*}(s) = R(s) + \gamma \max_a \sum_{s'} p(s' | a, s) U^{\pi^*}(s')$$

How can we use this to solve for actual values of  $U(s)$ ?

- This is a system of *nonlinear* equations (because of max)
- Instead of asserting equality, what if we used it as an **update**?

Bellman **Update**:

$$U^{(i+1)}(s) \leftarrow R(s) + \gamma \max_a \sum_{s'} p(s' | a, s) U^{(i)}(s')$$

# Value Iteration - algorithm

```
def Value_Iteration():  
    Initialize U  
    for i in iterations:  
        Initialize new_U  
        for s in states:  
            new_U(s) = R(s) + gamma* max(sum(p(s' | a, s)*U(s')))  
        U = new_U  
        Optionally break once convergence criteria met
```

(figure 17.4 in text)

Iteratively apply the Bellman update until we converge or run out of iterations

**Convergence check** (not needed for project)

$$\|U^{(i+1)} - U^{(i)}\| < \epsilon(1 - \gamma)/\gamma \implies \|U^{(i+1)} - U^{\pi^*}\| < \epsilon$$

# Value Iteration - convergence proof (1)

How do we know just applying the Bellman update over and over again will eventually converge to the correct utilities?

## Notation

$$U^{(i+1)}(s) \leftarrow R(s) + \gamma \max_a \sum_{s'} p(s' \mid a, s) U^{(i)}(s')$$

$$U^{(i+1)} \leftarrow B[U^{(i)}]$$

We call this “applying the Bellman operator”

**Definition**  $\left\| U^{(i+1)} - U^{(i)} \right\| = \max_s \left| U^{(i+1)}(s) - U^{(i)}(s) \right|$

## Value Iteration - convergence proof (2)

**FACT:** The Bellman operator is a **contraction**

$$\|B[U] - B[U']\| \leq \gamma \|U - U'\|$$

This means applying the Bellman operator brings any two  $U$ 's closer together (for hints at why, see exercise 17.6)

## Value Iteration - convergence proof (3)

**Definition:** If  $B[U] = U$ ,  $U$  is called a **fixed point** of the operator  $B$  (applying the operator doesn't change anything)

**FACT:** Any contraction can have at most 1 fixed point

Assume  $U \neq V$  are both fixed points

$$\|B[U] - B[V]\| \leq \gamma \|U - V\|$$

$$\|U - V\| \leq \gamma \|U - V\|$$

$$\implies \|U - V\| = 0$$

$$\implies U = V \quad \text{contradiction!}$$

# Value Iteration - convergence proof (4)

So the Bellman operator is a contraction, it can have **at most** one fixed point. How does that help?

The Bellman **equation** tells us that  $U^{\pi^*}$  is a fixed point of the Bellman **operator**!

## Bellman Equation

$$U^{\pi^*}(s) = R(s) + \gamma \max_a \sum_{s'} p(s' | a, s) U^{\pi^*}(s')$$

## Bellman Update

$$U^{(i+1)}(s) \leftarrow R(s) + \gamma \max_a \sum_{s'} p(s' | a, s) U^{(i)}(s')$$

# Value Iteration - example (1)

**States**  $\{s_1, s_2, s_3, s_4\}$

**Actions** {up, down, left, right}

**Transition probability:** “0.8 correct, 0.1 perp”

$p(s_4 | R, s_1) = 0.8, p(s_1 | R, s_1) = 0.1$

**Rewards:** “1.0 for  $s_4$ , -0.04 for others”

**Discount:** 0.5

**Initial U:** 0.1

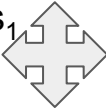

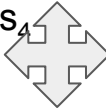

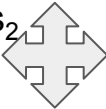

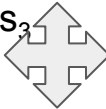

**Initial  $\pi$ :** any action

$s_1$ R=-0.04	$s_4$ R=1.0
$s_2$ R=-0.04	$s_3$ R=-0.04

Initial U

$s_1$ U=.1	$s_4$ U=.1
$s_2$ U=.1	$s_3$ U=.1

Initial  $\pi$

$s_1$ 	$s_4$ 
$s_2$ 	$s_3$ 

# Value Iteration - example (2)

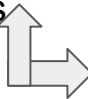

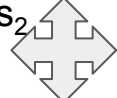

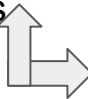

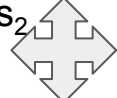

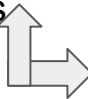

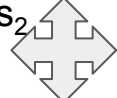

$$U^{(i+1)}(s) \leftarrow R(s) + \gamma \max_a \sum_{s'} p(s' | a, s) U^{(i)}(s')$$

## Iteration 1

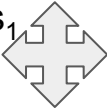

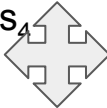

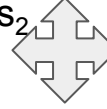

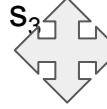

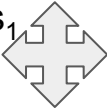

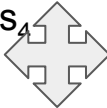

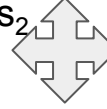

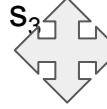

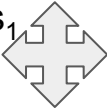

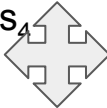

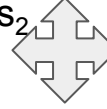

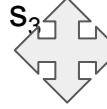

$$U^{(1)}(s_1) = -0.04 + (0.5) * \max\{ \dots 0.1 \dots \} = 0.01$$

$$U^{(1)}(s_2) = U^{(1)}(s_3) = 0.01$$

$$U^{(1)}(s_4) = 1.0 + (0.5) * \max\{ \dots 0.1 \dots \} = 1.05$$

# Value Iteration - example (3)

$$U^{(i+1)}(s) \leftarrow R(s) + \gamma \max_a \sum_{s'} p(s' | a, s) U^{(i)}(s')$$

## Iteration 2

$$U^{(2)}(s_1) = -0.04 + (0.5) * \max\{$$

$$U: (0.9)(0.01) + (0.1)(1.05)$$

$$(0.0)(0.01) + (0.0)(0.01) = 0.114$$

$$D: (0.1)(0.01) + (0.1)(1.05) +$$

$$(0.8)(0.01) + (0.0)(0.01) = 0.114$$

$$L: (0.9)(0.01) + (0.0)(1.05) +$$

$$(0.1)(0.01) + (0.0)(0.01) = 0.01$$

$$R: (0.1)(0.01) + (0.8)(1.05) +$$

$$(0.1)(0.01) + (0.0)(0.01) = 0.8423 \}$$

$$U^{(2)}(s_1) = -0.04 + (0.5) * (0.8423) = 0.381$$

s <sub>1</sub> R=-0.04	s <sub>4</sub> R=1.0
s <sub>2</sub> R=-0.04	s <sub>3</sub> R=-0.04

U <sup>(1)</sup>
------------------

s <sub>1</sub> U=.01	s <sub>4</sub> U=1.05
s <sub>2</sub> U=.01	s <sub>3</sub> U=.01

# Value Iteration - example (4)

$$U^{(i+1)}(s) \leftarrow R(s) + \gamma \max_a \sum_{s'} p(s' | a, s) U^{(i)}(s')$$

## Iteration 2

$$U^{(2)}(s_1) = 0.381$$

$$U^{(2)}(s_2) = -0.04 + (0.5)(0.01) = -0.035$$

$$U^{(2)}(s_3) = 0.381 \text{ (symmetric w/ } s_1)$$

$$U^{(2)}(s_4) = 1.0 + (0.5) \max\{$$

$$\text{U: } (0.1)(0.01) + (0.9)(1.05) = 0.946$$

D: low

L: low

$$\text{R: } 0.946 \text{ (symmetric w/ U) } \} = 1.0 + 0.473$$

$$U^{(2)}(s_4) = 1.473$$

s <sub>1</sub> R=-0.04	s <sub>4</sub> R=1.0
s <sub>2</sub> R=-0.04	s <sub>3</sub> R=-0.04

U <sup>(2)</sup>		U <sup>(1)</sup>	
s <sub>1</sub> U=.381	s <sub>4</sub> U=1.47	s <sub>1</sub> U=.01	s <sub>4</sub> U=1.05
s <sub>2</sub> U=-.035	s <sub>3</sub> U=.381	s <sub>2</sub> U=.01	s <sub>3</sub> U=.01

# Value Iteration - notes

We found the correct policy after just two iterations!

But our utility function hadn't converged yet...

## Notes

- Policy tends to converge faster than utility
- Each iteration only updates utility from states “one hop away:” may take a long time to propagate from goal
- If we could “fix” the policy, the max operator would go away, and the Bellman update would be linear

$s_1$ $R=-0.04$	$s_4$ $R=1.0$
$s_2$ $R=-0.04$	$s_3$ $R=-0.04$

# Policy Iteration

If the policy is fixed, the Bellman equation becomes

$$U^\pi(s) = R(s) + \gamma \sum_{s'} p(s' | \pi(s), s) U^\pi(s')$$

We can use this to implement `Policy_Eval()` as either a simplified version of Value Iteration, or by solving a system of linear equations

```
def Policy_Iteration():
    Initialize U, policy
    for i in iterations:
        new_U = Policy_Eval(policy, U)
        for s in states:
            a' = argmax(sum( p(s' | a, s) * new_U[s'] ))
            if a' is better than old policy with new_U:
                new_policy[s] = a'
            else:
                new_policy[s] = policy[s]
        if policy[s] = new_policy[s] for all s:
            break
    else
        policy = new_policy
```

# Summary and preview

## Wrapping up

- The Bellman equation gives us a way to compute the **utility** of the optimal policy, which in turn gives us a way to **find** the optimal policy
- Value Iteration is an iterative method that is **guaranteed** to converge to the optimal **utility** values
- Policy Iteration can potentially **speed up** this process, by keeping the policy fixed and using a simplified form of Bellman
